Polypropylene (PP-r) pipe systems vs copper environmental impact comparison

An independent study following ISO 14040 and 14044 methodology by the respected Flemish institute for Technological Research (VITO), and validated by the Denkstatt sustainable development institute in Austria, is conclusive in its findings that plastic pipe systems made from PP-r for plumbing hot and cold solid wall applications have a lower environmental impact than those made from copper.

To make a fair comparison between these two different materials and determine the environmental impacts of both, each stage of their lifecycle was analysed.

“Environmental footprints” can be either adverse or beneficial. Adverse effects such as omitting greenhouse gases may arise in either the product’s production or disposal process; beneficial effects help to reduce greenhouse gas emissions by saving energy whilst the product is in use.

DETERMINING A PRODUCT’S ENVIRONMENTAL FOOTPRINT

A scientifically-based full Life Cycle Assessment (LCA) is the standardised method for fairly comparing the environmental impacts of different products or services. This type of assessment involves systematically collecting and evaluating quantitative data on the inputs and outputs of material, energy and waste flows associated with a product over its entire life cycle. Therefore a whole range of processes need to be assessed to calculate overall impacts, beginning with the manufacturing of raw materials, to transforming them into products; continuing through the product’s transportation and installation, the product’s lifetime of use, and ultimately, the product’s disposal or re-processing at the end of life.

More detailed information about this material comparison can be obtained via www.teppfa.eu or by contacting TEPPFA at: info@teppfa.eu
The findings of LCA assessments are typically published in the forms of Environmental Product Declarations (EPDs) to help communicate a product’s overall environmental impact. The VITO study involved collecting data on plastic pipe systems from companies covering more than 50% of the European market. Data for copper was based on publicly available information.

**ENVIRONMENTAL IMPACT CRITERIA**

The environmental impact of each pipe material was assessed against seven different criteria across its full life cycle.

- ‘Abiotic-depletion’ non-fossil: the over-extraction of minerals and other non-living, non-renewable materials that can lead to exhaustion of natural resources.

- ‘Abiotic-depletion’ fossil: The over-extraction of fossil fuels including all fossil resources.

- ‘Acidiﬁcation’ potential: emissions, such as sulphur dioxide and nitrogen oxides, from manufacturing processes, result in acid rain which harms soil, water supplies, human and animal organisms, and the ecosystem.

- ‘Eutrophication’ potential: which arises from the over-fertilisation of water and soil by nutrients (such as nitrogen and phosphorous). This speeds up plant growth and kills off animal life in lakes and waterways.

- ‘Global warming’ potential (its carbon footprint): the insulating effect of greenhouse gases - CO2 and methane - in the atmosphere is a major contributor to global warming, affecting both human health and that of the ecosystem in which we live.

- ‘Ozone-depletion’ potential: depletion of the ozone layer in the atmosphere caused by the emission of chemical foaming and cleaning agents allows the passage of greater levels of UV from the sun, causing skin cancer and reducing crop yields.

- ‘Photochemical-oxidation’ potential: where the photochemical reaction of sunlight with primary air pollutants such as volatile organic compounds and nitrogen oxides leads to chemical smogs that affect human health, food crops and the ecosystem in general.

**COMPARISON BASED ON IDENTICAL FUNCTIONAL UNITS**

For the purpose of a direct fair comparison between alternative materials the following identical functional unit was used in the LCA study for plumbing hot and cold solid wall systems:

- The pressure supply and transport of hot and cold drinking water from entrance of an apartment of 100m² to the tap.

- a 50 year lifetime has been assumed which aligns with the normal lifetime expectancy of a building
